

# RHIC Results on $J/\psi$

Mike Leitch - LANL - [leitch@bnl.gov](mailto:leitch@bnl.gov)  
QM06 - Shanghai - 18 November 2006

## Production

- cross section & polarization
- feed-down

## Cold nuclear matter (CNM)

- shadowing or gluon saturation
- absorption & gluon energy loss
- $p_T$  broadening
- lack of  $x_2$  scaling

## Hot-dense matter in A+A collisions

- final PHENIX AuAu results
- cold nuclear matter effects in A+A
- regeneration & sequential suppression

## Upsilons

## Summary

(see talks by A. Bickley, A. Glenn, T. Gunji  
on Saturday afternoon - 2.1)

# J/ $\psi$ production, parton level structure & dynamics

## Production of heavy vector mesons, J/ $\psi$ , $\psi'$ and $\Upsilon$

**Gluon fusion** dominates (NLO calculations add more complicated diagrams, but still mostly with gluons)

- color **singlet or octet**  $c\bar{c}$ : absolute cross section and polarization? Difficult to get both correct!

**Configuration of  $c\bar{c}$**  (important for pA cold nuclear matter effects)

Complications due to substantial **feed-down** from higher mass resonances, from  $\psi'$ ,  $\chi_c$

- feed-down poorly known

$\chi_{1,2} \rightarrow J/\psi$	$\sim 30\%$
$\psi' \rightarrow J/\psi$	5.5%

# J/ψ Production - Polarization

- Octet models get correct cross section size (unlike singlet), but...
- CDF and Fermilab E866 J/ψ data show **zero or longitudinal polarization** & disagree with NRQCD predictions of large transverse polarization at large  $p_T$

$$d\sigma/d\cos\theta = A(1 + \lambda \cos^2\theta)$$

$$\begin{aligned}\lambda &= +1 \text{ (transverse)} \\ &= -1 \text{ (longitudinal)}\end{aligned}$$

**Is feed-down washing out polarization?**  
 (~40% of J/ψ from feed-down)  
 (good  $\psi'$  polarization measurement would be helpful here)

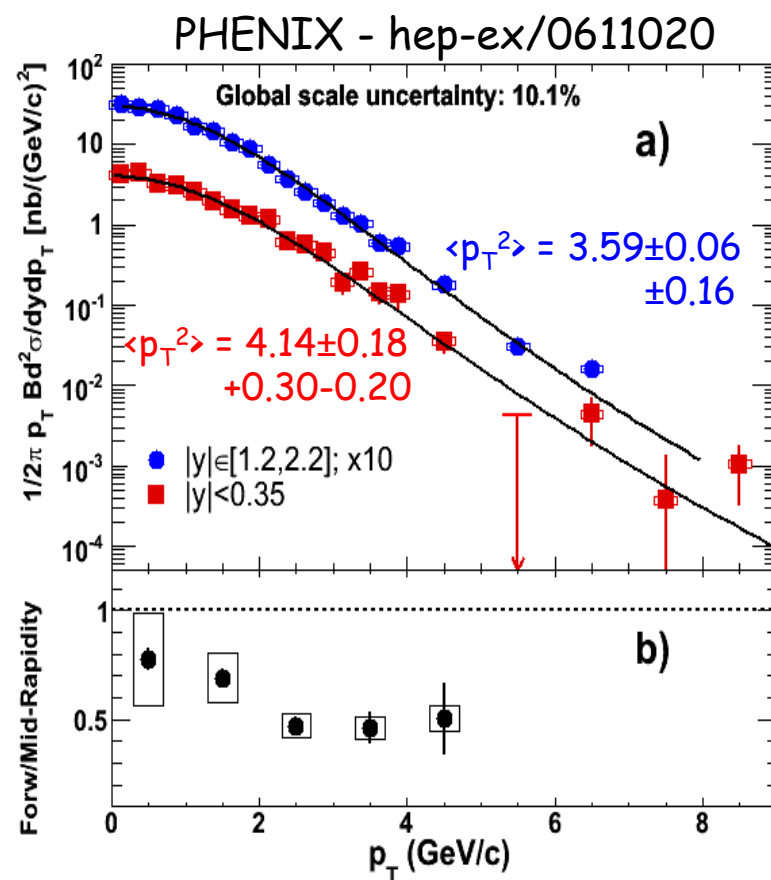

# PHENIX - p+p J/ψ - new run5 data

- Slightly favors flatter shape at mid-rapidity than most models
- Forward rapidity falloff steeper than 3-gluon pQCD model - black curve [Khoze et al. , Eur. Phys. J. C39, 163-171 (2005)]

•  $BR \cdot \sigma_{tot} = 178 \pm 3 \pm 53 \pm 18 \text{ nb}$

- Harder  $p_T$  than lower energy & softer at forward rapidity

# Cold Nuclear Matter (CNM) Effects Gluon Shadowing and Saturation

## Leading twist gluon shadowing

- e.g. "FGS", Eur. Phys. J A5, 293 (1999)

## Phenomenological fit to DIS & Drell-Yan data

- e.g. "EKS", Nucl. Phys. A696, 729 (2001).

## Coherence approach and many others

Amount of gluon shadowing differs by up to a factor of three between diff models!

## Saturation or Color Glass Condensate (CGC) - see F. Gelis talk

- At low- $x$  there are so many gluons that  $2 \rightarrow 1$  diagrams become important and deplete low- $x$  region
- Nuclear amplification:  $x_A G(x_A) = A^{1/3} x_p G(x_p)$ , i.e. gluon density is  $\sim 6\times$  higher in Gold than the nucleon

# Cold Nuclear Matter Effects Absorption & Energy Loss

$J/\psi$  suppression is a puzzle with possible contributions from **shadowing** & from:

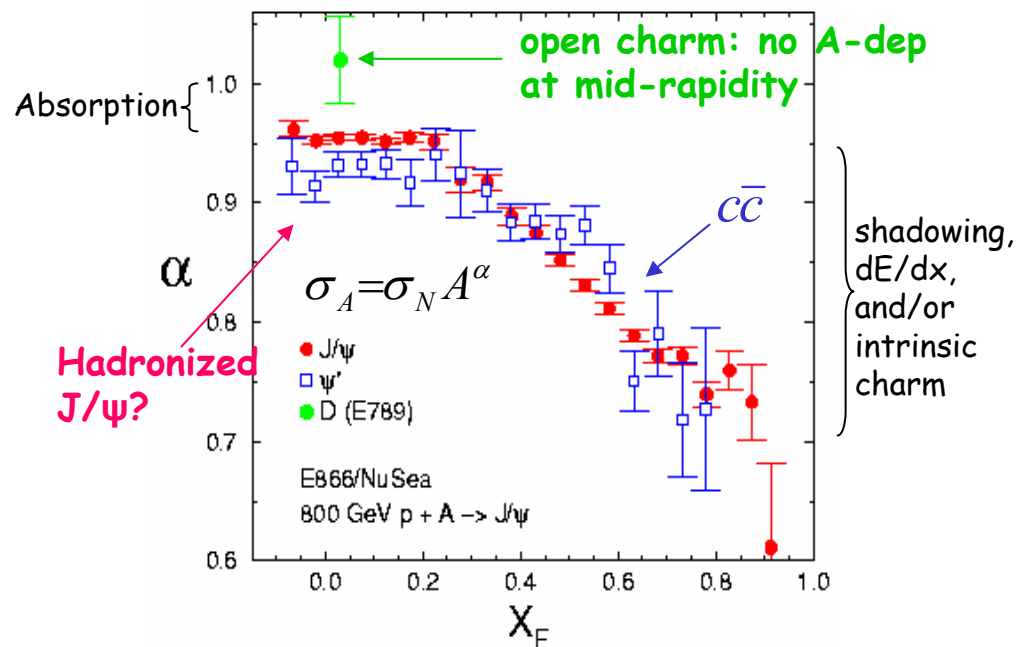

**Absorption** (or dissociation) of  $c\bar{c}$  into two D mesons by nucleus or co-movers (the latter most important in AA collisions where co-movers more copious)

**Energy loss** of incident gluon shifts effective  $x_F$  and produces nuclear suppression which increases with  $x_F$

800 GeV p-A (FNAL)  
*PRL* 84, 3256 (2000); *PRL* 72, 2542 (1994)

# Cold Nuclear Matter

## Transverse Momentum Broadening

$$\sigma_A = \sigma_N A^\alpha$$

Initial-state gluon multiple scattering causes  $p_T$  broadening (or Cronin effect)

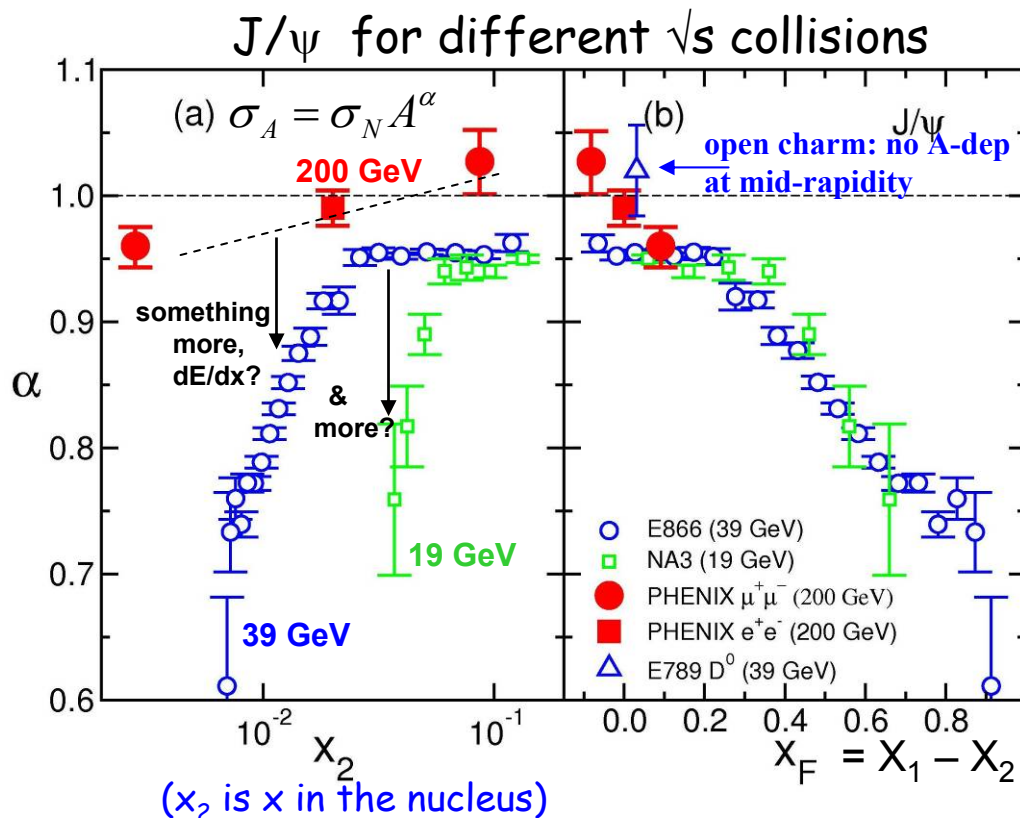

# PHENIX J/ψ Nuclear Dependence 200 GeV dAu collisions - PRL 96, 012304 (2006)

Klein, Vogt, PRL 91:142301, 2003

Data favors weak shadowing & absorption

- With limited statistics difficult to disentangle nuclear effects
- Need another dAu run!

Not universal vs  $x_2$  as expected for shadowing, but does scale with  $x_F$ , why?

- initial-state gluon energy loss?
- Sudakov suppression (energy conservation)?

# AuAu J/ψ's - Quark Gluon Plasma (QGP) signature?

**Debye screening** predicted to destroy J/ψ's in a QGP with different states "melting" at different temperatures due to different binding energies.

NA50  
anomalous  
suppression

**regeneration**  
models give  
enhancement that  
compensates for  
screening?

on the other hand, recent  
lattice calculations suggest  
**J/ψ not screened after all.**  
Suppression only via feed-down  
from screened  $\chi_c$  &  $\psi'$

# PHENIX Run4 AuAu final results (nucl-ex/0611020)

## 1st high statistics $J/\psi$ measurements at RHIC

- most central collisions suppressed to  $\sim 0.2$
- **forward** suppressed more than **mid-rapidity**
  - saturation of **forward/mid** suppression ratio rapidity @  $\sim 0.6$  for  $N_{\text{part}} \geq 100$ ?
  - trend opposite to that of CNM (solid lines) and comover (dashed) models

Also CuCu preliminary results (open circles) follow AuAu trend vs centrality for  $N_{\text{part}}$  below  $\sim 100$

# J/ $\psi$ suppression in AA collisions & CNM baseline (CNM = Cold Nuclear Matter)

200 GeV d+Au  $\rightarrow$  J/ $\psi$   
Vogt expanding octet absorption

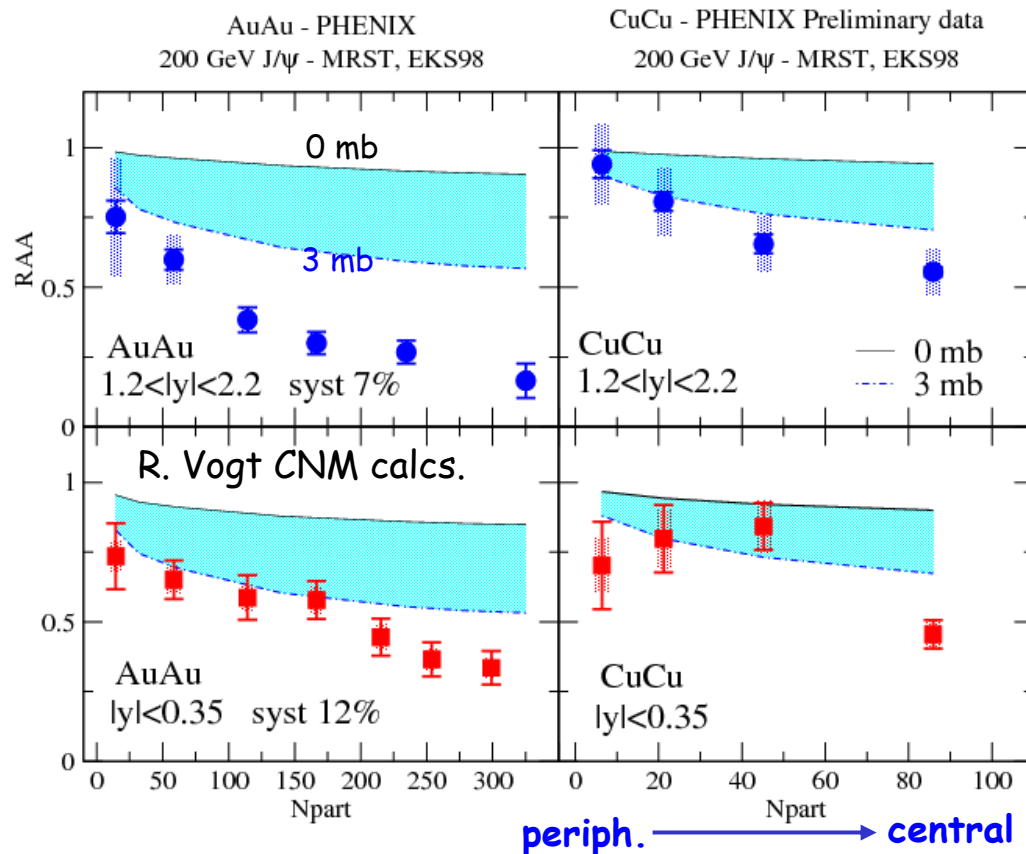

- CNM calculations with shadowing & absorption - R. Vogt, nucl-th/0507027

- present dAu data probably only constrains absorption to:  $\sigma_{\text{ABS}} \sim 0\text{-}3$  mb

See also talks by R. Vogt & R. Granier de Cassagnac  
Saturday (2.1) & Sunday(3.1) afternoons

11/21/2006

- AuAu suppression is stronger than CNM calculations predict especially for most central mid-rapidity & at forward rapidity

Mike Leitch

11

# Models without regeneration

**Models that reproduce NA50 results at lower energies (above):**

- Satz - color screening in QGP (percolation model) with CNM added (EKS shadowing + 1 mb)
- Capella - comovers with normal absorption and shadowing
- Rapp - direct production with CNM effects (without regeneration)

But predict too much suppression for RHIC mid-rapidity (at right)!

# Regeneration

At RHIC with 10x collision energy  
& 2-3x gluon energy density  
relative to SPS  $\rightarrow$  stronger QGP  
suppression at RHIC expected

- in regeneration models single charm quarks combine in the later stages to form  $J/\psi$ 's
- can compensate for strong QGP suppression to come near  $y=0$  RHIC data
- regeneration would be much larger at the LHC!
- but this regeneration goes as the (single) charm density which is poorly known at RHIC (another story, see A. Suaide's talk)

# Sequential Screening

(Karsch, Kharzeev, Satz, hep-ph/0512239)

Sequential screening only of the higher-mass resonances that feed-down to the  $J/\psi$ ; with the  $J/\psi$  itself still not dissolved?

- supported by recent Lattice calculations that give  $T_{J/\psi} > 2 T_c$
- gives similar suppression at RHIC & SPS (for mid-rapidity)

**But carefull!** Hard to know how to set relative energy density for RHIC vs SPS

$$\epsilon_{Bj} = \frac{dE_T}{dy} \frac{1}{\tau_0 \pi R^2}$$

- $\tau_0 > 1 \text{ fm/c}$  @ SPS?
- 1.6 fm/c crossing time
- $\tau_0$  smaller @ RHIC?

Quarkonium dissociation temperatures - Digal, Karsch, Satz

state	$J/\psi(1S)$	$\chi_c(1P)$	$\psi'(2S)$	$\Upsilon(1S)$	$\chi_b(1P)$	$\Upsilon(2S)$	$\chi_b(2P)$	$\Upsilon(3S)$
$T_d/T_c$	2.10	1.16	1.12	$> 4.0$	1.76	1.60	1.19	1.17

- Suppression stronger than possible from  $\psi'$ ,  $\chi_c$  alone?
- Gluon saturation can lower **forward** relative to **mid-rapidity**?

# Sequential Screening Scenario

- QGP suppression of  $\chi_c, \psi'$
- + additional forward suppression from gluon saturation (CGC)
- but approx. flat forward/mid above  $N_{part} \sim 100$  seems inconsistent - forward should drop more for more central collisions as gluon saturation increases

# Regeneration Scenario

- both forward & mid rapidity suppressed by QGP - i.e. screening or large gluon density
- mid-rapidity suppression reduced by strong regeneration effect
- but approx. flat **forward/mid** suppression for  $N_{\text{part}} > 100$  seems inconsistent with increasing regeneration & increasing QGP suppression for more central collisions

Need comprehensive theoretical work that puts sequential screening, regeneration, gluon saturation, forward suppression of open charm, etc. ALL TOGETHER - and considers experimental uncertainties carefully

# Regeneration should cause narrowing of $p_T$ - does it?

- $\langle p_T^2 \rangle$  pretty flat for both mid and forward-y
- as expected in regeneration picture of Thews
- Yan picture almost flat to start with, gives slight fall-off with centrality

Caution -  $\langle p_T^2 \rangle$  from fits often unreliable for AA  
(stable when restricted to  $p_T < 5$  GeV/c here)  
Better for theoretical comparisons to look at  $R_{AA}(p_T)$ ?

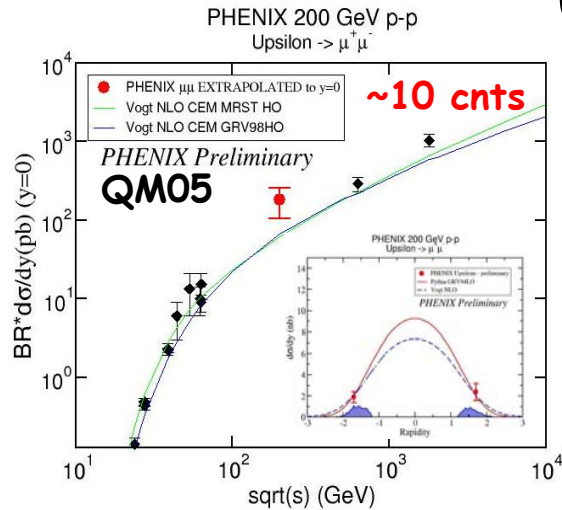

# Regeneration should give J/ψ Flow

Open charm has recently been seen to flow (at least at some  $p_T$  values)

Need to look for J/ψ flow - if regeneration dominates, the J/ψ's should inherit flow from charm quarks

# Upsilons at RHIC

Signal	RHIC Exp. (Au+Au)	RHIC I (>2008)	RHIC II	LHC ALICE <sup>+</sup>
$J/\psi \rightarrow e^+e^-$	PHENIX	3,300	45,000	9,500
$J/\psi \rightarrow \mu^+\mu^-$		29,000	395,000	740,000
$\Upsilon \rightarrow e^+e^-$	STAR	830	11,200	2,600
$\Upsilon \rightarrow \mu^+\mu^-$	PHENIX	80	1,040	8,400

PHENIX QM05 - 1st Upsilons at RHIC  
from  $\sim 3\text{pb}^{-1}$  collected in the 2005 run.

# Summary - J/ $\psi$ Suppression

## A puzzle of two (or more) ingredients

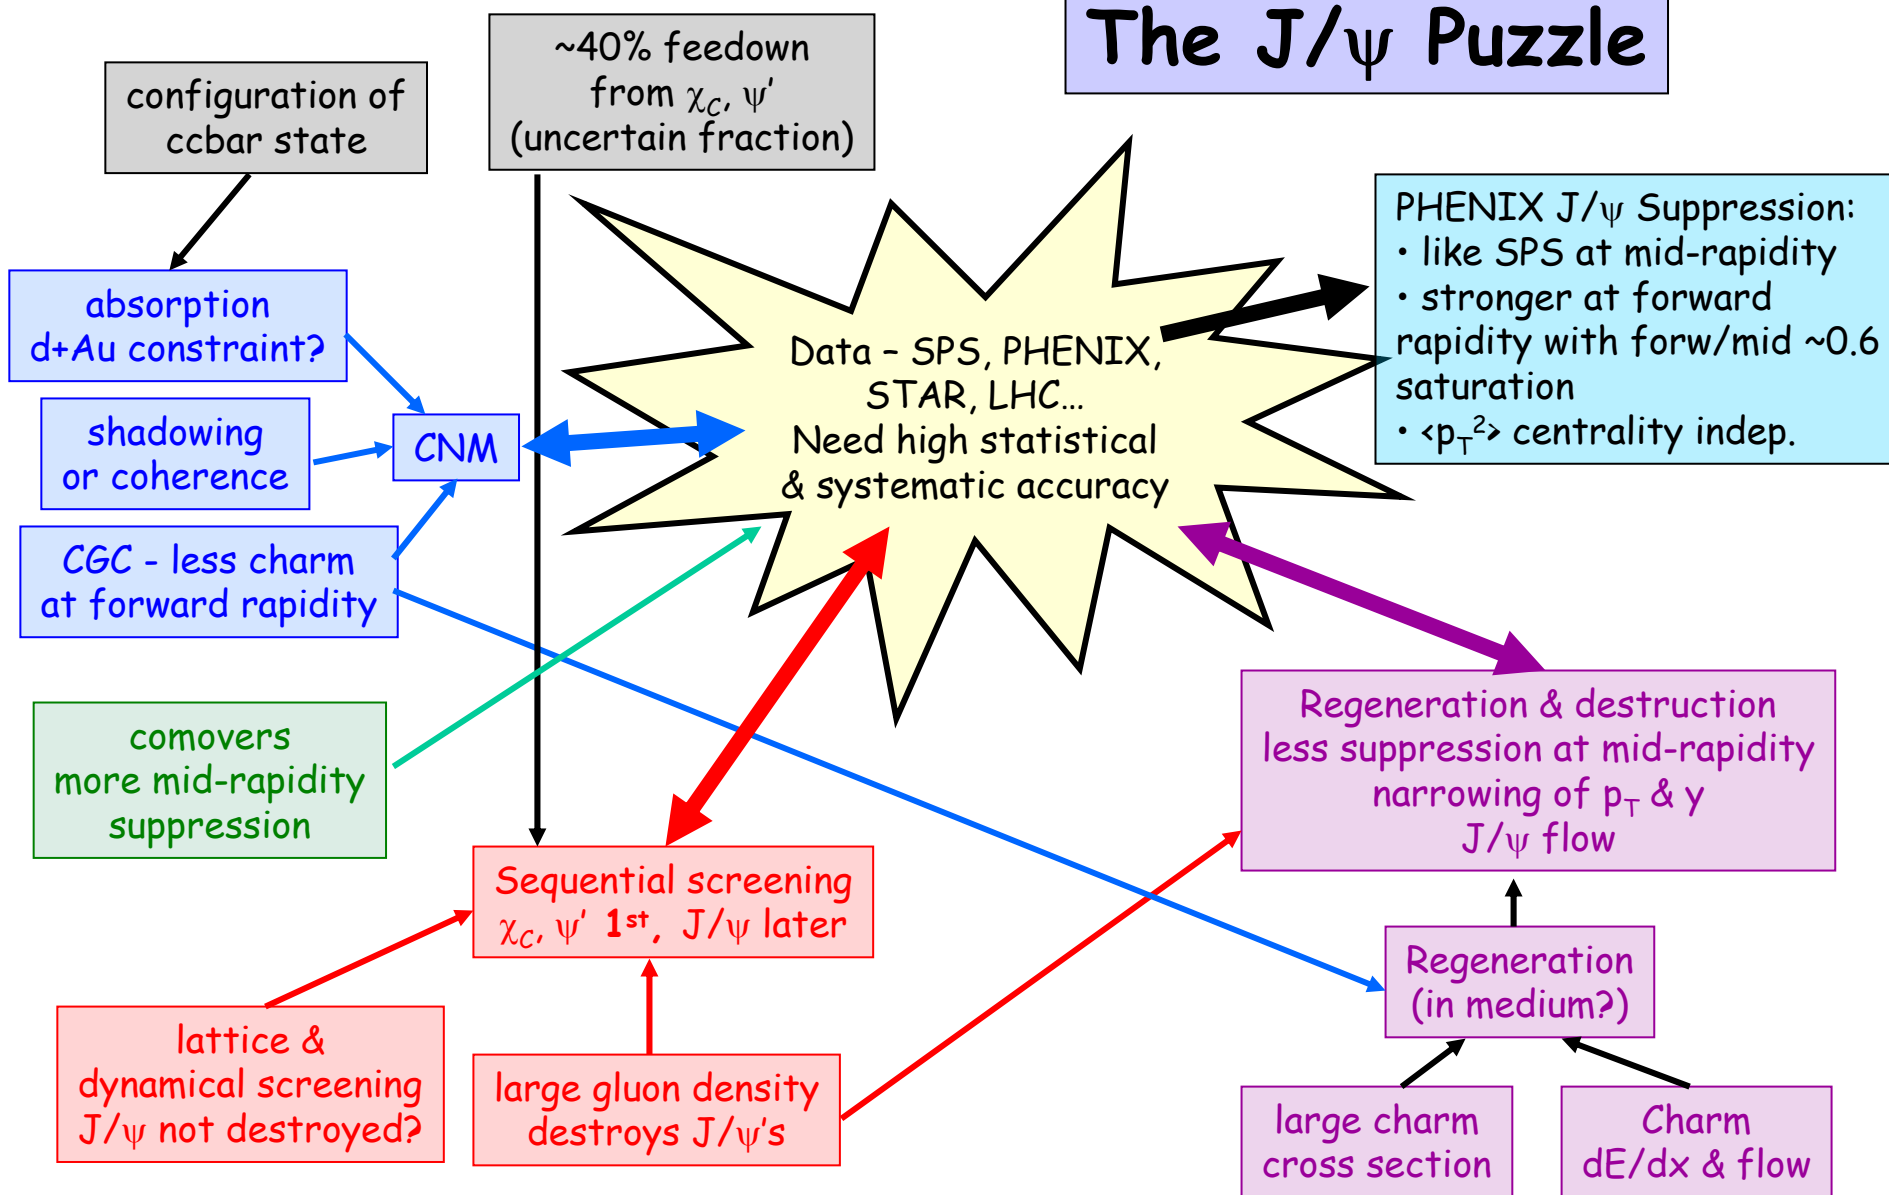

Sequential screening and forward- $y$  gluon saturation?

difficult to compare RHIC to SPS suppression - but may be similar

# BACKUP

# The J/ψ Puzzle

CNM effects, constrained by dAu data, give fairly flat rapidity dependence in AuAu

Comparison of  
QM05  
preliminary AuAu  
results (open  
circles) to final  
results (closed  
circles).

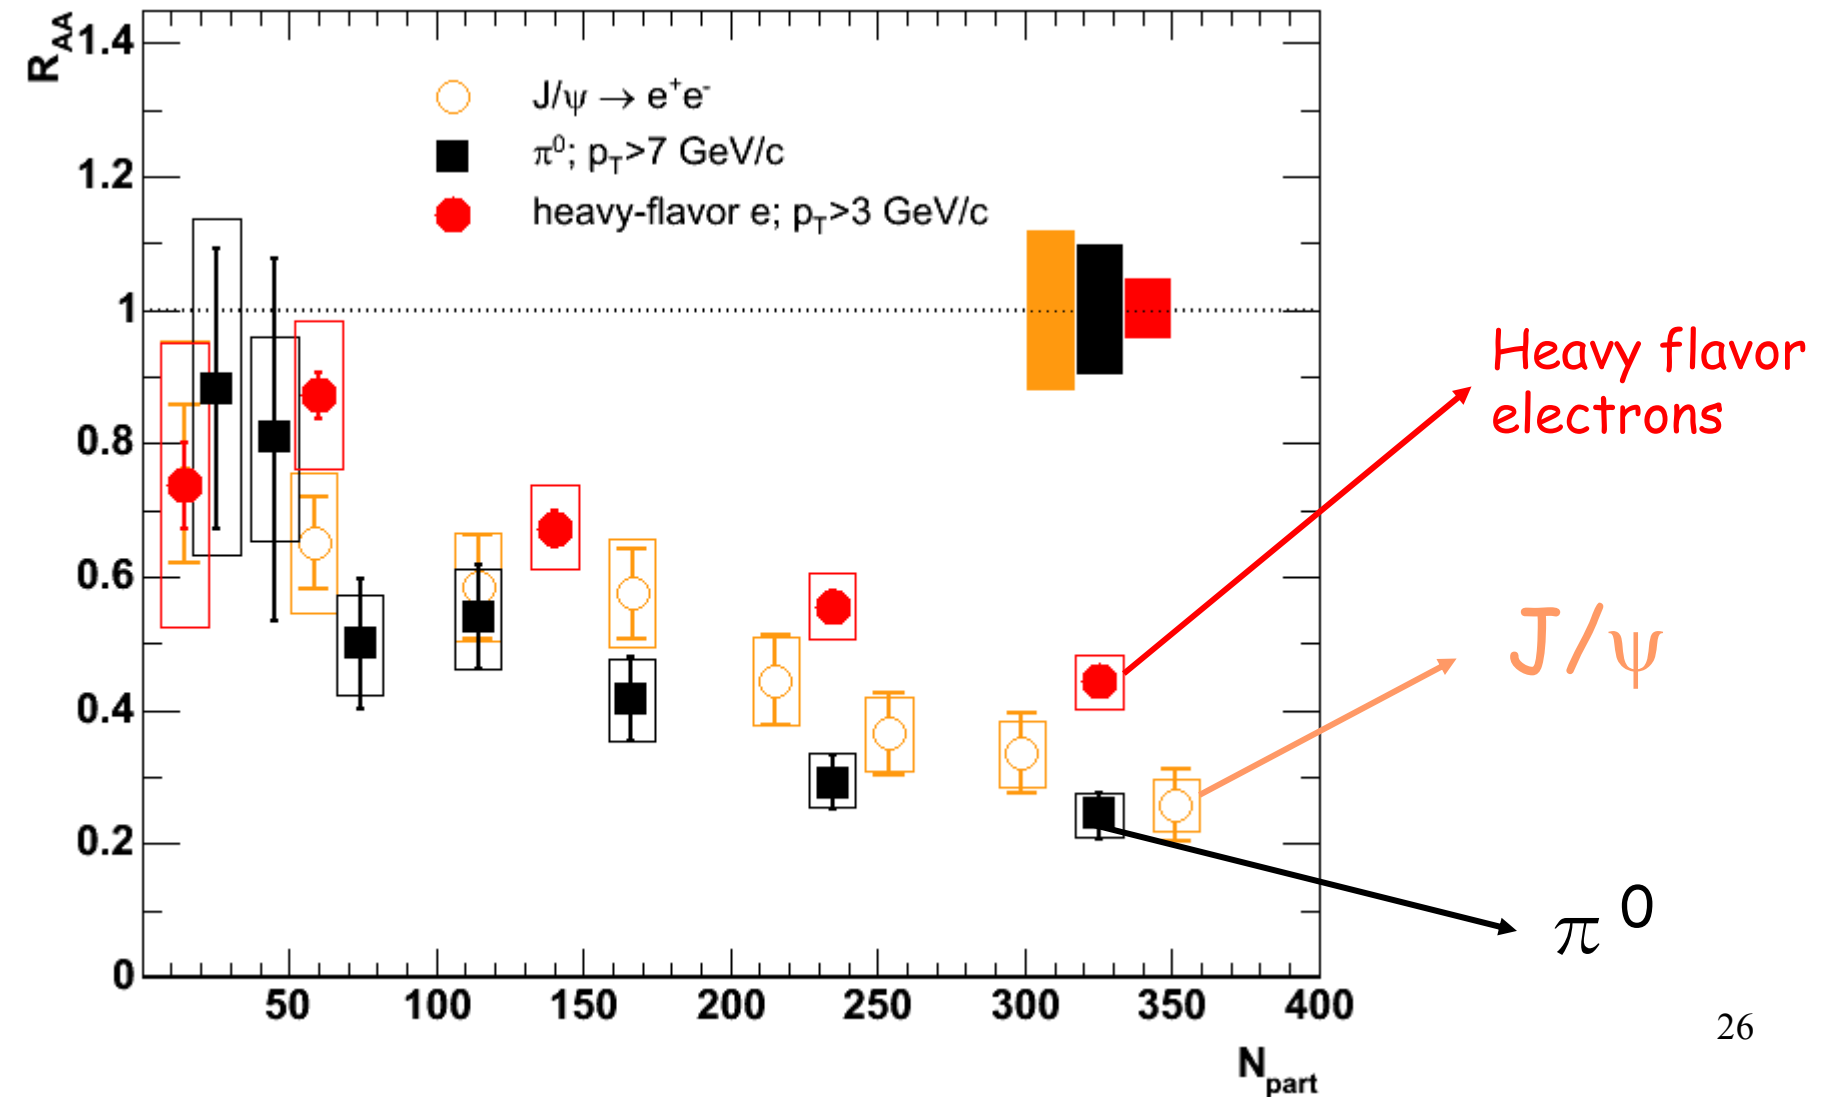

Red mid rapidity  
Blue forward  
rapidity

# $R_{AA}$ or $R_{AA}/CNM$ vs Number of Participants

# $J/\psi$ suppression vs. light hadrons

# Many More Models for RHIC J/ $\psi$ suppression in AuAu Collisions

All have suppression + various regeneration mechanisms

Rapp - PRL 92, 212301 (2004)

- screening & in-medium production

Thews - see previous slide

Andronic - PL B57, 136 (2003)

- statistical hadronization model
- screening of primary J/ $\psi$ 's
- + statistical recombination of thermalized c-cbar's

Kostyuk - PRC 68, 041902 (2003)

- statistical coalescence
- + comovers or QGP screening

Bratkovskaya - PRC 69, 054903 (2004)

- hadron-string dynamics transport

Zhu - PL B607, 107 (2005)

- J/ $\psi$  transport in QGP
- co-movers, gluon breakup, hydro for QGP evolution
- no cold nuclear matter, no regeneration

# Detector Upgrades for Heavy Quarks

## PHENIX

- Silicon vertex detector
  - mid-rapidity & forward heavy-q's, incl.  $B \rightarrow J/\psi X$
  - improved background & mass resolution for quarkonia & dimuons
- Nose cone calorimeter  $\chi_c \rightarrow J/\psi \gamma$

## RHIC-II

- Luminosity increases via electron cooling also important:
  - $\times 10$  (AuAu);  $\times 2-3$  (pp)

## STAR

- Silicon vertex detectors
- Heavy Flavor Tracker & integrated central tracker
- $D \rightarrow K\pi$

# RHIC-II - Quarkonia

- With detector upgrades (PHENIX and STAR):
  - $J/\psi$  from  $B$  decays with displaced vertex measurement (both).
  - Reduce  $J/\psi \rightarrow \mu\mu$  background with forward vertex detector in PHENIX.
  - Improve mass resolution for charmonium and resolve  $\Upsilon$  family.
  - See  $\chi_c$  by measuring  $\gamma$  in forward calorimeter in front of muon arms (PHENIX)
- And with the luminosity upgrade:
  - Measure  $B \rightarrow J/\psi$  using displaced vertex - independent  $B$  yield measurement, also get background to prompt  $J/\psi$  measurement.
  - $J/\psi R_{AA}$  to high  $p_T$ . Does  $J/\psi$  suppression go away at high  $p_T$ ?
  - $J/\psi v_2$  measurements versus  $p_T$ . See evidence of charm recombination?
  - $\Upsilon R_{AA}$ . Which Upsilon's are suppressed at RHIC?
  - Measure  $\psi' R_{AA}$ . Ratio to  $J/\psi$ ?
  - Measure  $\chi_c \rightarrow J/\psi + \gamma R_{AA}$ . Ratio to  $J/\psi$ ?

# Onia Yields at RHIC II

Signal/System	pp (200 GeV)	pp (500 GeV)	CuCu (200 GeV)	AuAu (200 GeV)	dAu (200 GeV)
$J/\Psi \rightarrow ee$	55,054	609,128	73,921	44,614	29,919
$\Psi'(2S) \rightarrow ee$	993	10,985	1,333	805	540
$\chi_{c0} \rightarrow \gamma + J/\Psi \rightarrow ee$	100	2,578	134	81	54
$\chi_{c1} \rightarrow \gamma + J/\Psi \rightarrow ee$	1,340	40,870	1,800	1,086	728
$\chi_{c2} \rightarrow \gamma + J/\Psi \rightarrow ee$	2,190	59,296	2,941	1,775	1,190
$\Upsilon(0,1,2) \rightarrow ee$	210	3,032	547	397	184
$B \rightarrow J/\Psi \rightarrow ee$	1,237	41,480	4,567	3,572	1,085
$J/\Psi \rightarrow \mu\mu$	468,741	5,483,006	653,715	394,535	258,136
$\Psi'(2S) \rightarrow \mu\mu$	8,453	98,880	11,789	7,115	4,655
$\chi_{c0} \rightarrow \gamma + J/\Psi \rightarrow \mu\mu$	3,822	99,824	5,330	3,217	2,105
$\chi_{c1} \rightarrow \gamma + J/\Psi \rightarrow \mu\mu$	51,215	1,582,561	71,425	43,107	28,204
$\chi_{c2} \rightarrow \gamma + J/\Psi \rightarrow \mu\mu$	83,702	2,296,069	116,732	70,451	46,095
$\Upsilon(0,1,2) \rightarrow \mu\mu$	528	7,723	1,429	1,035	469
$B \rightarrow J/\Psi \rightarrow \mu\mu$	2079	76466	5756	3752	1824

- Precision measurements of the  $J/\Psi$
- Exploratory measurements of the other onium states.
- Steep increase at  $\sqrt{s} = 500$  GeV illustrates the significant difficulties for measurements at lower energies.
